Abstract

The *EIF1AX* gene mutations have been recently found in papillary thyroid carcinoma (PTC) and anaplastic thyroid carcinoma (ATC). The prevalence of these mutations in other types of thyroid cancers and benign nodules is unknown. In this study, we analyzed the occurrence of *EIF1AX* mutations in exons 2, 5, and 6 of the gene in a series of 266 thyroid tumors and hyperplastic nodules by either Sanger or next-generation sequencing (ThyroSeq v.2). In addition, 647 thyroid fine-needle aspiration (FNA) samples with indeterminate cytology were analyzed. Using surgically removed samples, *EIF1AX* mutations were detected in 3/86 (2.3%) PTC, 1/4 (25%) ATC, 0/53 follicular carcinomas, 0/12 medullary carcinomas, 2/27 (7.4%) follicular adenomas, and 1/80 (1.3%) hyperplastic nodules. Among five mutation-positive FNA samples with surgical follow-up, one nodule was PTC and others were benign follicular adenomas or hyperplastic nodules. Overall, among 33 mutations identified, A113_splice mutation at the intron 5/exon 6 splice site of *EIF1AX* was the most common. All four carcinomas harbored A113_splice mutation and three of them had one or more coexisting mutations, typically *RAS*. All PTC carrying *EIF1AX* mutations were encapsulated follicular variants. In summary, this study shows that *EIF1AX* mutations occur not only in thyroid carcinomas, but also in benign nodules. The most common mutation hotspot is the A113_splice, followed by a cluster of mutations in exon 2. When found in thyroid FNA samples, *EIF1AX* mutations confer ~20% risk of cancer; the risk is likely to be higher in nodules carrying a A113_splice mutation and when *EIF1AX* coexists with *RAS* mutations.

Endocrine-Related Cancer
(2016) 23, 295–301

Introduction

Thyroid cancer is the most common endocrine cancer and its incidence is increasing in the USA and other countries due to improved detection of indolent thyroid cancers by sensitive imaging techniques and possibly due to other factors (Davies & Welch 2006, Brito *et al.* 2013, Jung *et al.* 2014). Cytological diagnosis of thyroid nodules using cells collected by fine-needle aspiration (FNA) is the most reliable way of cancer diagnosis, but a significant proportion of FNA samples is placed in indeterminate cytological category, preventing optimal

patient management (Haugen *et al.* 2016). Advances in sequencing technology coupled with better understanding of the molecular mechanisms of thyroid tumorigenesis have led to increasing use of genomic testing for clinical management of patients with thyroid nodules (Adeniran *et al.* 2006, Cantara *et al.* 2010, Nikiforov *et al.* 2011). Recently, The Cancer Genome Atlas (TCGA) study on a large cohort of papillary thyroid carcinomas (PTC) reported mutations of the *EIF1AX* gene in these tumors (Cancer Genome Atlas Research 2014c).

The *EIF1AX* gene located on chromosome X and codes for an eukaryotic translation initiation factor 1A (eIF1A). The protein promotes 43S complex formation by stabilizing the binding of the ternary complex eIF2-GTP-methionyl-initiator tRNA to the 40S subunit and, together with other translation initiation factor is involved in a sophisticated scanning system responsible for accurately locating the proper start codon on the mRNA in eukaryotes (Pestova et al. 2001, Olsen et al. 2003, Fekete et al. 2005, Hinnebusch 2014). eIF1A is the eukaryotic ortholog of bacterial translation initiation factor IF1, with sequences between 32 and 95 amino acids constituting the RNA-binding domain that are homologous to IF1. Additional domains in eIF1, absent in IF1, are a helical domain adjacent to the RNA-binding fold and long and highly charged unstructured N- and C-terminal tails (NTT, CTT). The CTT is primarily negatively charged but contains a few hydrophobic residues at the very end that were proposed to be involved in protein-protein interactions (Fekete et al. 2007, Saini et al. 2010). Mutations of residues on the RNA-binding surface of eIF1A are reported to cause defects in proper 43S and 48S preinitiation complex formation (Battiste et al. 2000). Prior to TCGA study of PTC, mutations in *EIF1AX* gene were reported in uveal melanomas (Martin et al. 2013, Ewens et al. 2014). A recent study also reported *EIF1AX* mutations in anaplastic thyroid carcinomas (ATC) (Kunstman et al. 2015). However, the prevalence of these mutations in other common types of thyroid cancer, such as follicular carcinoma, and in benign thyroid nodules remains unknown. Furthermore, histopathologic characteristics of thyroid tumors harboring *EIF1AX* mutations are not well characterized. The aim of this study was to determine the prevalence of *EIF1AX* mutations in all major types of thyroid tumors and benign nodules, spectrum of *EIF1AX* mutation, and histopathologic characteristics of thyroid lesions harboring *EIF1AX* mutations.

Materials and methods

Study cases

This study was approved by the University of Pittsburgh Institutional Review Board. Two groups of samples were studied. The first group included 266 surgical specimens (formalin-fixed paraffin-embedded and snap-frozen tissue samples) that were used to study the prevalence of *EIF1AX* mutations in various types of thyroid nodules. The second group included 647 consecutive fine-needle aspiration (FNA) samples with indeterminate cytology genotyped during a 2-month time interval.

Table 1 Prevalence of *EIF1AX* mutations in thyroid nodules.

Histopathologic diagnosis	Total cases	<i>EIF1AX</i> mutation positive (%)
Papillary thyroid carcinoma	86	2 (2.3)
Follicular thyroid carcinoma	53	0
Poorly differentiated thyroid carcinoma	4	0
Anaplastic thyroid carcinoma	4	1 (25)
Medullary thyroid carcinoma	12	0
Follicular adenoma	27	2 (7.4)
Hyperplastic nodule	80	1 (1.3)

Histologic review

Glass slides of surgical resection of all cases positive for *EIF1AX* mutation were retrieved from the archives of the Department of Pathology, University of Pittsburgh Medical Center and reviewed to confirm histopathologic diagnosis and tumor variant, and to assess for other salient features.

Molecular analysis

Testing for *EIF1AX* mutations in exons 2, 5, and 6 was performed using Sanger sequencing or next-generation sequencing panel (ThyroSeq v2) as previously described (Nikiforov et al. 2014). In addition to *EIF1AX*, the panel included the analysis of point mutations in the hotspots of 13 other thyroid cancer-related genes (*AKT1*, *BRAF*, *NRAS*, *HRAS*, *KRAS*, *PTEN*, *TP53*, *GNAS*, *CTNNB1*, *RET*, *PIK3CA*, *TERT*, and *TSHR*) and gene fusions in the *RET*, *BRAF*, *NTRK1*, *NTRK3*, *ALK*, *PPARG*, and *THADA* genes. For some samples, Sanger sequencing was performed on ABI13130 (Applied Biosystems) for exons 2, 5, and 6 of *EIF1AX* gene. For targeted next-generation sequencing analysis, the custom primers were designed using a Life

Table 2 Location and type of *EIF1AX* mutations found in thyroid nodules.

Mutated codon	Frequency (%)	Mutation variants	Coexisting mutations
Codon 113	15 (46)	A113_splice	<i>NRAS</i> , <i>HRAS</i> , <i>TP53</i>

Green circles denotes missense mutations and red circles denotes splice-site mutations. A full colour version of this figure is available at <http://dx.doi.org/10.1530/ERC-16-0043>.

Technologies design tool to generate a pool of primers for amplification of genomic regions of interest. Library concentration and amplicon size were determined using an Agilent BioAnalyzer High Sensitivity DNA Kit (Agilent Technologies). Next, multiplexed barcoded libraries were enriched by clonal amplification using emulsion PCR on Ion Sphere particles (Ion PGM Template OT2 200 Kit, Thermo Fisher Scientific) and loaded on an Ion 318 Chip. Massively parallel sequencing was carried out on a Personal Genome Machine sequencer (Ion Torrent) using the Ion PGM Sequencing 200 Kit version 2 according to the manufacturer's instructions.

Results

First, the prevalence of *EIF1AX* mutation was assessed in a series of surgically resected thyroid nodules representing all common types of thyroid cancer. Among 86 surgical PTC samples, two specimens were positive for *EIF1AX* mutations, resulting in an overall frequency of 2.3%. Both mutations were a splice-site mutation located in the intron 5/exon 6 junction of *EIF1AX* gene (A113_splice). Analysis of eight dedifferentiated carcinomas (including four poorly

differentiated carcinomas and four anaplastic carcinomas) identified an A113_splice mutation in one ATC. Analysis of 53 follicular thyroid carcinomas (FTC), which included 22 oncocyctic (Hürthle cell) variants of follicular carcinomas, did not reveal *EIF1AX* mutations. Similarly, no *EIF1AX* mutation was identified in 12 medullary carcinomas. Screening of benign thyroid nodules detected *EIF1AX* mutations in two (7.4%) follicular adenomas (FA) and one (1.3%) hyperplastic thyroid nodules (Table 1).

Next, the analysis was performed on 647 consecutive thyroid FNA cytology samples with indeterminate cytology, of which 27 (4.2%) were found to be positive for *EIF1AX* mutations. Of the *EIF1AX*-positive cytology specimens, 63% had a diagnosis of atypia of undetermined significance/follicular lesion of undetermined significance, 30% had a diagnosis of follicular neoplasm/suspicious for follicular neoplasm, and 4% had a diagnosis of suspicious for malignancy. Follow-up thyroidectomy specimens were available in 5 of the 27 samples. Histopathologically, the *EIF1AX*-positive nodules yielded the diagnosis of PTC in one case, follicular adenoma in three cases, and hyperplastic thyroid nodule in one case. Out of 27 thyroid nodules positive for *EIF1AX* mutations in FNA samples, 21 nodules had no coexisting

mutations, whereas 6 nodules had additional mutations. Of those, four nodules showed presence of a coexisting *NRAS* codon 61 mutation, one sample had a *HRAS* codon 61 mutation, and one had a *GNAS* mutation. Of these six cases, one nodule harboring *EIF1AX* and *NRAS* mutation was surgically excised to reveal the encapsulated follicular variant of PTC.

Overall, in the two sample groups, 33 *EIF1AX* mutations were identified (Table 2). All mutations were single nucleotide substitutions that were clustered in two areas of the gene, either in codons 6–15 located in the unstructured NTT (54%) or codon 113 corresponding to the unstructured CTT (46%) of the *EIF1AX* (Fig. 1). Codon 113 was split by intron 5 and harbored the most common *EIF1AX* mutation identified in 15 (46%) of *EIF1AX*-positive cases. These were splice-site mutations affecting one of the two consensus intronic nucleotides (c.338-1A and c.338-2G) located in the splice site of intron 5/exon 6. The second most common mutation, found in eight (24%) cases, affected codon 9, leading to the substitution of glycine by arginine, aspartic acid, or valine. *EIF1AX* codon 13 missense mutations were identified in four (12%) cases and resulted in the amino acid substitution of arginine to leucine, aspartic acid, or proline. Less common mutations affected codons 8, 10, and 15, all being missense mutations, while a single case showed a splice-site mutation at codon 6, which was split by intron 1.

A total of 11 cases that harbored *EIF1AX* mutation were available for histopathology review (Table 3). The size of these thyroid nodules ranged from 1.3 to 6.0 cm

(mean, 2.9 cm) and histopathologic diagnoses included PTC in three cases, ATC in one case, follicular adenoma in five cases, and hyperplastic thyroid nodule in five cases (Table 3).

All three mutation-positive PTCs carried the same *EIF1AX* A113_splice mutation. Two of these tumors also harbored a coexisting mutation of *NRAS*. The tumor nodules ranged in size from 1.5 to 6.0 cm. Microscopically, they had a complete thin or thick capsule and follicular growth pattern characteristic of the encapsulated follicular variant of PTC (Fig. 2). The neoplastic follicles in each nodule varied in size with abundant colloid and were lined by cells showing moderate to prominent nuclear features of PTC. A tumor with isolated *EIF1AX* mutation showed focal capsular invasion (Fig. 2), whereas other tumors showed no tumor capsule or vascular invasion. None of the PTCs carrying the *EIF1AX* mutation had extrathyroidal extension or lymph node metastasis.

One ATC case was positive for the *EIF1AX* A113_splice mutation found in combination with *NRAS* Q61R, *TERT* C228T, and *TP53* E180* stop codon mutation. Microscopic examination of the excised tumor revealed a combination of epithelioid, spindle cell, and multinucleated giant cell growth patterns and large areas of necrosis. No well-differentiated component was observed.

Five FA were found to harbor *EIF1AX* mutations, including A113_splice site ($\times 2$), G9R/V ($\times 2$), and K10N. The nodules ranged in size from 1.3 to 3.5 cm, had a thin to thick capsule, and typically a mixture of small- to normal-sized follicles (Fig. 3A and B). Two adenomas were

Figure 3

Histopathologic features of *EIF1AX*-positive benign thyroid nodules. (A, B) A follicular adenomas surrounded by a thin fibrous capsule (A) and showing small- to normal-sized follicles lined by cells with round, uniform nuclei and dark chromatin. (A, H&E, $\times 20$; B, H&E, $\times 400$). (C, D) Hyperplastic thyroid nodule with a thin capsule and a mixture of normal- and large-sized follicles with abundant colloid. (C, H&E, $\times 20$; D, H&E, $\times 400$). A full colour version of this figure is available at <http://dx.doi.org/10.1530/ERC-16-0043>.

of conventional type and one showed oncocytic (Hürthle cell) morphology. Two additional *EIF1AX*-positive nodules were diagnosed as hyperplastic nodules. Both of them harbored a G9R *EIF1AX* mutation. The nodules had a thin capsule and were composed of predominantly large follicles with abundant colloid (Fig. 3C and D).

Discussion

The results of this study confirm the presence of *EIF1AX* mutations in PTC and ATC and demonstrate for the first time that these mutations also occur in benign thyroid nodules. Furthermore, we show that *EIF1AX* mutations may coexist with other driver mutations such as *RAS* and *TP53*, which is found more frequently in malignant nodules.

The frequency of *EIF1AX* mutations in PTC found in this study is comparable to that reported by TCGA (Cancer Genome Atlas Research 2014c), indicating that *EIF1AX* mutations are reproducibly found in 1–2% of these tumors. Most of the *EIF1AX*-mutated PTCs (5/6 cases; 83%) in TCGA study were registered as follicular variants (Gao et al. 2013). The sixth PTC case also showed follicular components, but with predominant classic PTC features explained by the presence of *BRAF* V600E mutation in addition to *KRAS* Q61K and *EIF1AX* mutations. Similarly, in our study all three PTCs were follicular variants, and all were encapsulated. This indicates that the follicular variant of PTC, typically encapsulated, is a typical phenotype of *EIF1AX*-mutated PTC.

Since the follicular variant of PTC is known to share genetic alterations with other follicular-patterned thyroid tumors, that is, FTC and FA (Nikiforov & Nikiforova 2011), it was important to understand if *EIF1AX* mutations also occur in FTC and FA. Our analysis revealed no *EIF1AX* mutations in any of 53 FTC, but identified them in 7% of FA. Even though a complete absence of *EIF1AX* mutations in FTC cannot be ruled out, these results suggest that the prevalence of *EIF1AX* mutations in FTC is likely to be low. The finding of these mutations in FA raises a theoretical possibility that *EIF1AX*-mutated FA have a propensity to progress to the follicular variant of PTC rather than to FTC.

EIF1AX mutations appear to frequently coexist with other mutations, particularly *RAS*. In this study, co-occurrence of *NRAS* mutation was observed in three of four *EIF1AX*-mutated cancers, but not in any benign thyroid nodules. Similarly, combination of *EIF1AX* and *RAS* mutations was observed in previously reported PTC and ATC (Cancer Genome Atlas Research 2014c, Kunstman et al. 2015), and in other types of epithelial cancer and melanomas (Cerami et al. 2012, Gao et al. 2013, Cancer Genome Atlas Research 2014a,b). This raises a possibility that *EIF1AX* mutations alone are not sufficient for full transformation, but requires other mutations, particularly *RAS*, for progression to overt malignancy.

We identified a total of 33 samples harboring *EIF1AX* mutations that were clustered at exon 2 and intron 5 splice site. The two consensus nucleotides within intron 5 (c.338-1A, c.338-2G) immediately upstream to the exon 6 splice site is the most common and recurrent hotspot

for mutations. Of interest, four out of six thyroid nodules carrying this mutation were cancers in our study. Similar hotspot splice site mutation was also reported in two of six PTCs in TCGA study and two of four ATCs by Knutsman *et al.* (Cancer Genome Atlas Research 2014c, Kunstman *et al.* 2015, Chai *et al.* 2016). The EIF1AX A113_splice mutation affects the splicing of EIF1AX transcripts at the boundary of the helical domain within the C-strand and the highly charged unstructured CTT downstream involved in protein–protein interactions (Saini *et al.* 2010). Residues in the NTT and CTT of eIF1A act in opposite manner on scanning and start codon recognition and mutations in both NTT and CTT residues have been reported to impair preinitiation complex (PIC) assembly (Fekete *et al.* 2005, Saini *et al.* 2010). Nevertheless, an exact functional significance of codon 113 splice-site mutation that preserves RNA-binding domain, but altering the C-strand and CTT domains remains unclear.

Other common hotspot for EIF1AX mutations is exon 2, which codes for the unstructured NTT domain. Codon 9 mutations are most commonly affected at this site. Mutations involving codons 13, 10, 15, and intron 1/exon 2 splice site were also identified in this study, and those have not been previously reported in thyroid tumors. Mutations in exon 2 coding for the NTT segments were found to promote an open scanning conducive conformation of PIC leading to leaky scanning, but these mutations were located between residues 17–21 of the gene (Fekete *et al.* 2005, Saini *et al.* 2010). In this study, all nodules carrying a mutation affecting exon 2 were benign. However, exon 2 mutations were found to occur in four PTC in the TCGA study (Cancer Genome Atlas Research 2014c). Overall, the available data suggest that the EIF1AX p.A113_splice mutation confers a higher risk of cancer in a given nodule than the exon 2 mutations.

It is important to stress that not all patients with thyroid nodules underwent surgery, and therefore the histologic outcomes for those nodules were not available. This represents a limitation of the study.

In summary, we report here the occurrence of EIF1AX mutations not only in thyroid cancer, but also in benign thyroid nodules, and demonstrate that phenotypically these mutations are associated with the encapsulated follicular variant of PTC and benign follicular-pattern nodules. Furthermore, the presence of A113_splice mutation, particularly in combination with RAS mutation, is more frequently associated with thyroid cancer than isolated EIF1AX mutations or mutations located at other hotspots of the gene.
